

MAX77801

High-Efficiency Buck-Boost Regulator

General Description

The MAX77801 is a high-current, high-efficiency buck-boost targeted to mobile applications that use a Li-ion battery or similar chemistries. The MAX77801 utilizes a four-switch H-bridge configuration to support buck and boost operating modes. Buck-boost provides 2.60V to 4.1875V of output voltage range and up to 2A output current.

A unique control algorithm allows high efficiency, outstanding performances in line/load transient response, and seamless transition between buck and boost modes.

DVS (dynamic voltage scaling) input allows the host processor to switch between two preprogrammed output voltages. This feature minimizes power loss for given load conditions. The ramp-up and ramp-down slew rates are programmable through I²C.

The MAX77801 features I²C-compatible, 2-wire serial interface consisting of a bidirectional serial-data line (SDA) and a serial-clock line (SCL). It supports SCL clock rates up to 3.4MHz.

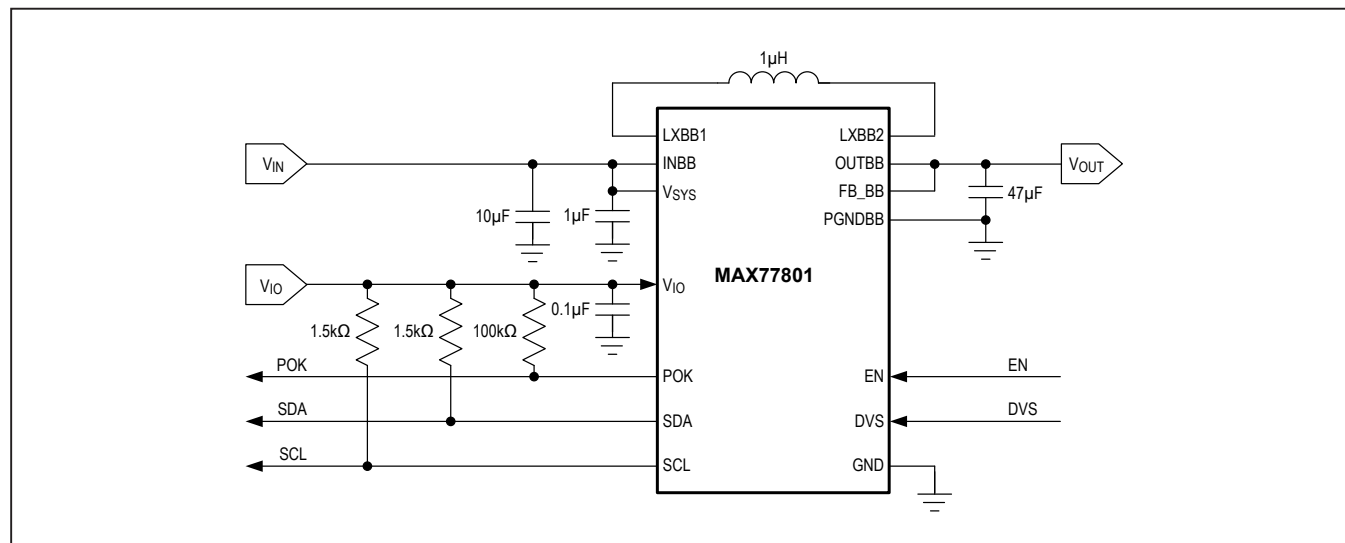

Applications

- Smartphones and Tablets
- Battery-Powered Applications

Benefits and Features

- 2A High-Efficiency Buck and Boost Operation Including Seamless Transition Between Buck and Boost Mode
- Flexibility Supports Various Designs
 - V_{OUT} Range from 2.60V to 4.1875V with 12.5mV Step
 - High-Speed (Up to 3.4MHz) I²C Serial Interface
- Low Quiescent Current, High Efficiency, and Dynamic Voltage Scaling Enable System to Be More Efficient
 - DVS Input
 - Up to 97% of Peak Efficiency
 - 55µA Quiescent Current
- High Switching Frequency and Small Package Reduce Solution Size
 - 2.5MHz Switching Frequency
 - 20-Bump WLP (0.4mm Pitch)
- Safety Features Enhance Device and System Reliability
 - POK Output
 - Soft-Start
 - True Shutdown™
 - Thermal Shutdown and Short-Circuit Protection

Typical Application Circuit

Ordering Information appears at end of data sheet.

True Shutdown is a trademark of Maxim Integrated Products, Inc.

Absolute Maximum Ratings

SYS, V _{IO} to GND.....	-0.3V to +6.0V	LXBB2 to PGNDDB.....	-0.3V to (V _{OUTBB} + 0.3V)
INBB, OUTBB to PGNDDB.....	-0.3V to +6.0V	LXBB1/LXBB2 Continuous RMS Current (Note 1).....	3.3A
PGNDDB to GND.....	-0.3V to +0.3V	Operating Temperature Range.....	-40°C to +85°C
SCL, SDA to GND.....	-0.3V to (V _{IO} + 0.3V)	Junction Temperature.....	+150°C
EN, DVS, POK to GND.....	-0.3V to (V _{SYS} + 0.3V)	Storage Temperature Range.....	-65°C to +150°C
FB_BB to GND.....	-0.3V to (V _{OUTBB} + 0.3V)	Soldering Temperature (reflow).....	+260°C
LXBB1 to PGNDDB.....	-0.3V to (V _{INBB} + 0.3V)		

Note 1: LXBB1/LXBB2 node has internal clamp diodes to PGNDDB and INBB. Applications that give forward bias to these diodes should ensure that the total power loss does not exceed the power dissipation limit of IC package.

Stresses beyond those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Package Thermal Characteristics (Note 2)

Junction-to Ambient Thermal Resistance (θ_{JA}).....55.49°C/W

Note 2: Package thermal resistances were obtained using the method described in JEDEC specification JESD51-7, using a four-layer board. For detailed information on package thermal considerations, refer to www.maximintegrated.com/thermal-tutorial.

Buck-Boost Electrical Characteristics

(V_{SYS} = V_{INBB} = +3.8V, V_{FB_BB} = V_{OUTBB} = +3.3V, T_A = -40°C to +85°C, typical values are at T_A = +25°C, unless otherwise noted.) (Note 3)

PARAMETER	SYMBOL	CONDITIONS	MIN	TYP	MAX	UNITS

Note 3: Limits are 100% production tested at T_A = +25°C. Limits over the operating temperature range are guaranteed through correlation using statistical quality control methods.

Note 4: Guaranteed by design. Not production tested.

Typical Operating Characteristics

($V_{SYS} = V_{INBB} = +3.8V$, $V_{FB_BB} = V_{OUTBB} = +3.3V$, $T_A = +25^{\circ}C$.)

Pin Configuration

Pin Description

PIN	NAME	FUNCTION
A1	V _{sys}	System (Battery) Voltage Input. Bypass to GND with a 1µF capacitor.
A2	DVS	Dynamic Voltage Scaling Logic Input. If not in use, then it must be connected to GND.
A3, B3	GND	Ground. Star-Ground Connection to System GND
A4	SDA	I ² C Data I/O (High Impedance in Off State). A 1.5kΩ~2.2kΩ of pullup resistor to V _{IO} is required.
A5	SCL	I ² C Clock Input (High Impedance in Off State). A 1.5kΩ~2.2kΩ of pullup resistor to V _{IO} is required.
B1	FB_BB	Buck-Boost Output Voltage Feedback
B2	POK	Power OK. Open-drain output asserted after buck-boost output reaches to 90% of output voltage. Polarity is factory selectable option. Active high by default.
B4	EN	Active-High, Buck-Boost External Enable Input. An 800kΩ internal pulldown resistance to the GND. If this pin is not used, leave it floating.
B5	V _{IO}	I ² C Supply Voltage Input. Bypass to GND with a 0.1µF capacitor. If not in use, connect to GND.
C1, D1	OUTBB	Buck-Boost Output
C2, D2	LXBB2	Buck-Boost Switching Node 2
C3, D3	PGNDBB	Buck-Boost Power Ground. Star-ground connection to system GND.
C4, D4	LXBB1	Buck-Boost Switching Node 1
C5, D5	INBB	Buck-Boost Input. Bypass to PGNDBB with a 10µF capacitor.

Detailed Description

Chip Enable (EN)

When EN pin goes high, the MAX77801 turns on the internal bias circuitry, which typically takes 85 μ s to settle. As soon as the bias is ready, buck-boost regulator is enabled. Once V_{IO} is supplied, then all user registers are accessible through I²C. When EN pin is pulled low, the MAX77801 goes into shutdown mode. This event also resets all type-O registers to their POR default values.

Immediate Turn-Off Events

The following events initiate immediate turn-off:

- Thermal protection ($T_J > +165^\circ\text{C}$)
- $V_{\text{SYS}} < V_{\text{SYS UVLO}}$ falling threshold ($V_{\text{UVLO_F}}$)
- Overcurrent protection

The events in this category disable buck-boost until the hazardous condition come back to normal conditions.

Regulator Enable Control

Buck-boost has GPIO enable pin EN as well as I²C enable bit. As shown in the [Table 1](#), the regulator should be enabled by EN and then it can be enabled or disabled by I²C control bit (AND logic) until EN remains in high.

Dynamic Voltage Scaling (DVS)

Buck-boost includes DVS feature that allows output voltage to change dynamically. The buck-boost output voltages are selected by DVS. When EN pin is asserted, the

Table 1. Enable Control Logic Truth Table

EN	BB_EN BIT	OPERATING MODE
low	x	Device off
high	0	Disable output
high	1 (default)	Enable output

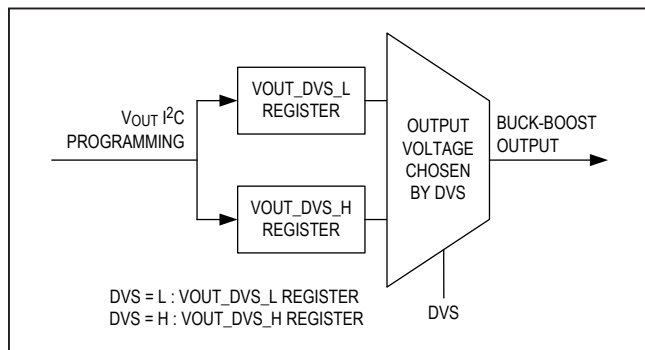

Figure 1. DVS Functional Block Diagram

status of DVS pin is latched until completing soft-start so that changes on DVS are ignored. After soft-start is done, internal logic sets V_{OUT} based on DVS input.

Buck-boost regulator supports a programmable slew-rate control feature when increasing and decreasing the output voltage. The ramp-up slew rate can be set to 12.5mV/ μ s or 25mV/ μ s through BB_RU_SR bit. Also, the ramp-down slew rate can be set to 3.125mV/ μ s or 6.25mV/ μ s through BB_RD_SR bit.

Power-OK (POK) Indicator

Buck-boost has an open-drain output that is asserted after the output voltage reaches 90%. The polarity of POK output is factory programmable option. It is active high by default.

Buck-Boost Regulator

When EN pin goes high, the MAX77801 turns on the internal bias circuitry, which typically takes 85 μ s to settle. As soon as the bias is ready, buck-boost regulator is enabled. Once V_{IO} is supplied, then all user registers are accessible through I²C. When EN pin is pulled low, the MAX77801 goes into shutdown mode. This event also resets all type-O registers to their POR default values.

H-Bridge Controller

H-bridge architecture operates at 2.5MHz fixed frequency with a pulse width modulated (PWM), current-mode control scheme. This topology is in a cascade of a boost regulator and a buck regulator using a single inductor and output capacitor. Buck, buck-boost, and boost stages are 100% synchronous for highest efficiency in portable applications.

There are three phases implemented with the H-bridge switch topology, as shown in [Figure 3](#):

- $\Phi 1$ switch period (Phase 1: HS1 = ON, LS2 = ON) stores energy in the inductor, ramping up the inductor current at a rate proportional to the input voltage divided by inductance, V_{INBB}/L .
- $\Phi 2$ switch period (Phase 2: HS1 = ON, HS2 = ON) ramps the inductor current up or down, depending on the differential voltage across the inductor, divided by inductance; $\pm(V_{\text{INBB}} - V_{\text{OUTBB}})/L$.
- $\Phi 3$ switch period (Phase 3: LS1 = ON, HS2 = ON) ramps down the inductor current at a rate proportional to the output voltage divided by inductance, $-V_{\text{OUTBB}}/L$.

Figure 2. Buck-Boost Block Diagram

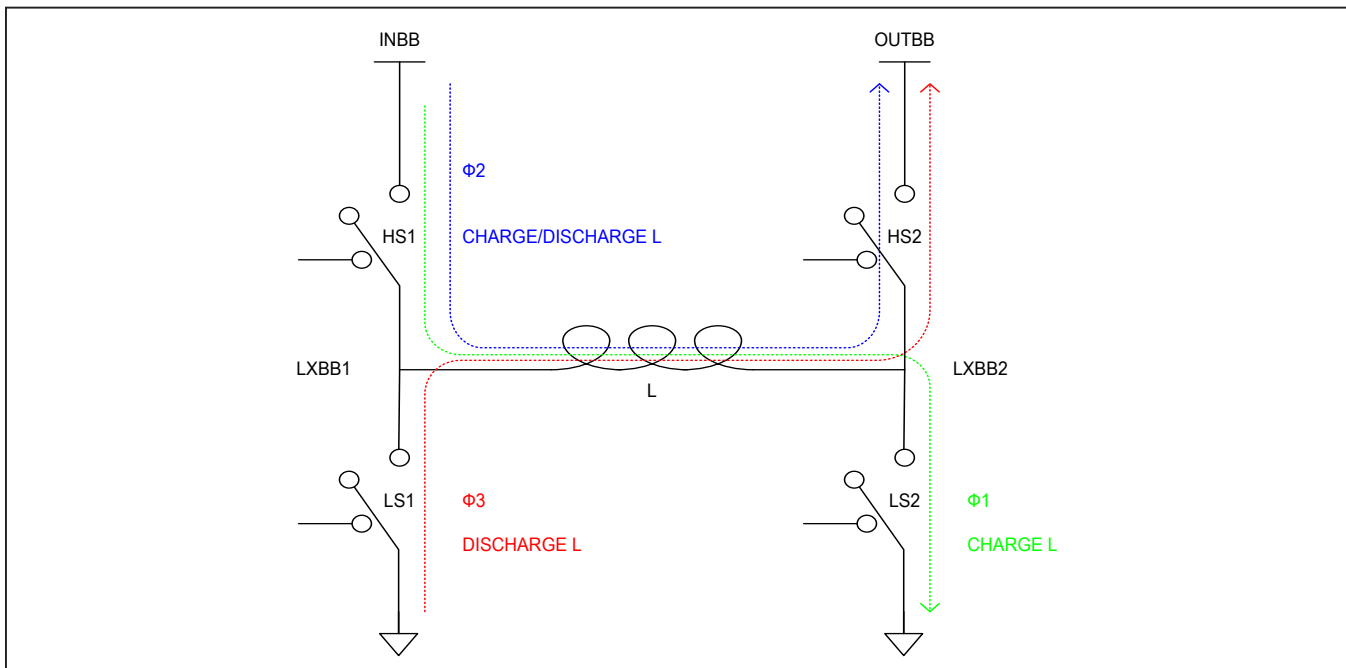

Figure 3. Buck-Boost Switching Intervals

2-phase buck topology is utilized when $V_{INBB} > V_{OUTBB}$. A switching cycle is completed in one clock period. Switch period $\Phi 2$ is followed by switch period $\Phi 3$, resulting in an inductor current waveform similar to [Figure 4](#).

2-phase boost topology is utilized when $V_{INBB} < V_{OUTBB}$. A switching cycle is completed in one clock period. Switch period $\Phi 1$ is followed by switch period $\Phi 2$, resulting in an inductor current waveform similar to [Figure 5](#).

Output Voltage Slew-rate Control

Buck-boost regulator supports programmable slew-rate control feature when increasing and decreasing the output voltage. The ramp-up slew-rate can be set to 12.5mV/ μ s or 25mV/ μ s through BB_RU_SR bit, while the ramp-down slew-rate is programmable to 3.125mV/ μ s or 6.25mV/ μ s through BB_RD_SR bit.

Output Active Discharge

Buck-boost provides an internal 100 Ω resistor for output active discharge function. If the active discharge function is enabled (BB_AD = 1), the internal resistor discharges the energy stored in the output capacitor to PGNDDB whenever the regulator is disabled.

Either the regulator remains enabled or the active discharge function is disabled (BB_AD = 0), the internal resistor is disconnected from the output. If the active discharge function is disabled, the output voltage decays at a rate that is determined by the output capacitance and the load current when the regulator is turned off.

Inductor Selection

Buck-boost is optimized for a 1 μ H inductor. The lower the inductor DCR, the higher buck-boost efficiency is. Users need to trade off inductor size with DCR value and choose a suitable inductor for buck-boost.

Input Capacitor Selection

The input capacitor, C_{IN} , reduces the current peaks drawn from the battery or input power source and reduces switching noise in the device. The impedance of C_{IN} at the switching frequency should be kept very low. Ceramic capacitors with X5R or X7R dielectrics are highly recommended due to their small size, low ESR, and small temperature coefficients. For most applications, a 10 μ F capacitor is sufficient.

Output Capacitor Selection

The output capacitor, C_{OUT} , is required to keep the output voltage ripple small and to ensure regulation loop stability. C_{OUT} must have low impedance at the switching frequency. Ceramic capacitors with X5R or X7R dielectric are highly recommended due to their small size, low ESR, and small temperature coefficients. For stable operation, buck-boost requires 16 μ F of minimum effective output capacitance. Considering DC bias characteristic of ceramic capacitors, a 47 μ F 6.3V capacitor is recommended for most of applications.

Serial Interface

I²C compatible 2-wire serial interface is used for regulator on/off control, setting output voltages, and other functions. See the *Register Map* section for details.

I²C serial bus consists of a bidirectional serial-data line (SDA) and a serial clock (SCL). I²C is an open-drain bus. SDA and SCL require pullup resistors (500Ω or greater). Optional 24Ω resistors in series with SDA and SCL help to protect the device inputs from high voltage spikes on the bus lines. Series resistors also minimize crosstalk and undershoot on bus lines.

System Configuration

I²C bus is a multimaster bus. The maximum number of devices that can attach to the bus is only limited by bus capacitance.

The figure above shows an example of a typical I²C system. A device on I²C bus that sends data to the bus is called a transmitter. A device that receives data from the bus is called a receiver. The device that initiates a data transfer and generates SCL clock signals to control

the data transfer is the master. Any device that is being addressed by the master is considered a slave. When the MAX77801 I²C-compatible interface is operating, it is a slave on I²C bus, and it can be both a transmitter and a receiver, too.

Bit Transfer

One data bit is transferred for each SCL clock cycle. The data on SDA must remain stable during the high portion of SCL clock pulse. Changes in SDA while SCL is high are control signals (START and STOP conditions).

START and STOP Conditions

When I²C serial interface is inactive, SDA and SCL idle high. A master device initiates communication by issuing a START (S) condition. A START condition is a high-to-low transition on SDA with SCL high. A STOP (P) condition is a low-to-high transition on SDA, while SCL is high.

A START condition from the master signals the beginning of a transmission to the MAX77801. The master terminates transmission by issuing a NOT ACKNOWLEDGE (nA) followed by a STOP condition.

Figure 6. Functional Logic Diagram for Communications Controller

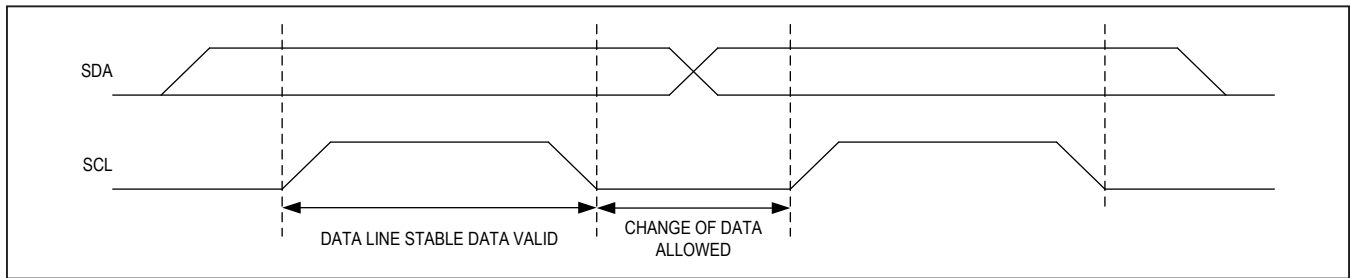

Figure 7. I²C Bit Transfer

Figure 8. START and STOP Conditions

STOP condition frees the bus. To issue a series of commands to the slave, the master may issue REPEATED START (Sr) commands instead of a STOP command in order to maintain control of the bus. In general, a REPEATED START command is functionally equivalent to a regular START command.

When a STOP condition or incorrect address is detected, the MAX77801 internally disconnects SCL from I²C serial interface until the next START condition, minimizing digital noise and feedthrough.

Acknowledge

Both I²C bus master and MAX77801 (slave) generate acknowledge bits when receiving data. The acknowledge bit is the last bit of each nine bit data packet. To generate an ACKNOWLEDGE (A), the receiving device must pull SDA low before the rising edge of the acknowledge-related clock pulse (ninth pulse) and keep it low during the high period of the clock pulse. To generate a NOT ACKNOWLEDGE, the receiving device allows SDA to be pulled high before the rising edge of the acknowledge-related clock pulse and leaves it high during the high period of the clock pulse.

Monitoring the acknowledge bits allows for detection of unsuccessful data transfers. An unsuccessful data transfer occurs if a receiving device is busy or if a system fault has occurred. In the event of an unsuccessful data transfer, the bus master should reattempt communication at a later time.

Slave Address

The I²C slave address of the MAX77801 is shown in [Table 3](#).

Clock Stretching

In general, the clock signal generation for the I²C bus is the responsibility of the master device. I²C specification allows slow slave devices to alter the clock signal by holding down the clock line. The process in which a slave device holds down the clock line is typically called clock stretching. The MAX77801 does not use any form of clock stretching to hold down the clock line.

General Call Address

The MAX77801 does not implement the I²C specification called general call address. If the MAX77801 sees a general call address (00000000b), it does not issue an ACKNOWLEDGE.

Communication Speed

The MAX77801 provides I²C 3.0-compatible (3.4MHz) serial interface.

- I²C revision 3-compatible serial communications channel
 - 0Hz to 100kHz (standard mode)
 - 0Hz to 400kHz (fast mode)
 - 0Hz to 1MHz (fast mode plus)
 - 0Hz to 3.4MHz (high-speed mode)
- Does not utilize I²C clock stretching

Operating in standard mode, fast mode, and fast mode plus does not require any special protocols. The main consideration when changing the bus speed through this range is the combination of the bus capacitance and pullup resistors. Higher time constants created by the bus capacitance and pullup resistance (C x R) slow the bus operation. Therefore, when increasing bus speeds, the pullup resistance must be decreased to maintain a reasonable time constant. Refer to the *Pullup Resistor Sizing* section of I²C revision 3.0 specification for detailed guidance on the pullup resistor selection. In general, for bus capacitances of 200pF, a 100kHz bus needs 5.6kΩ pullup resistors, a 400kHz bus needs about a 1.5kΩ pullup resistors, and a 1MHz bus needs 680Ω pullup resistors. Note that the pullup resistor is dissipating power when the open-drain bus is low. The lower the value of the pullup resistor, the higher the power dissipation (V²/R).

Table 3. I²C Slave Address

SLAVE ADDRESS (7 bit)	SLAVE ADDRESS (Write)	SLAVE ADDRESS (Read)
001 1000	0x30 (0011 0000)	0x31 (0011 0001)

Figure 9. Slave Address Byte Example

Operating in high-speed mode requires some special considerations. For the full list of considerations, refer to the I²C 3.0 specification. The major considerations with respect to the MAX77801 are:

- I²C bus master uses current source pullups to shorten the signal rise times.
- I²C slave must use a different set of input filters on its SDA and SCL lines to accommodate for the higher bus speed.
- The communication protocols need to utilize the high-speed master code.

At power-up and after each STOP condition, the MAX77801 input filters are set for standard mode, fast mode, or fast mode plus (i.e., 0Hz to 1MHz). To switch the input filters for high-speed mode, use the high-speed master code protocols that are described in *Communication Protocols* section.

Communication Protocols

The MAX77801 supports both writing and reading from its registers. The following sections show the I²C communication protocols for each functional block. The power block uses the same communications protocols.

Writing to a Single Register

The figure below shows the protocol for I²C master device to write one byte of data to the MAX77801. This protocol is the same as SMBus specification's write byte protocol.

The write byte protocol is as follows:

- 1) The master sends a START command.
- 2) The master sends the 7-bit slave address followed by a write bit ($R/\overline{W} = 0$).
- 3) The addressed slave asserts an ACKNOWLEDGE by pulling SDA low.
- 4) The master sends an 8-bit register pointer.
- 5) The slave acknowledges the register pointer.
- 6) The master sends a data byte.
- 7) The slave updates with the new data.

- 8) The slave acknowledges or does not acknowledge the data byte. The next rising edge on SDA loads the data byte into its target register, and the data becomes active.
- 9) The master sends a STOP condition or a REPEATED START condition. Issuing a STOP ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START leaves the bus input filters in their current state.

Writing to a Sequential Register

The figure below shows the protocol for writing to a sequential registers. This protocol is similar to the write byte protocol, except the master continues to write after it receives the first byte of data. When the master is done writing, it issues a STOP or REPEATED START. The writing to sequential registers protocol is as follows:

1. The master sends a START command.
2. The master sends the 7-bit slave address followed by a write bit ($R/\overline{W} = 0$).
3. The addressed slave asserts an ACKNOWLEDGE by pulling SDA low.
4. The master sends an 8-bit register pointer.
5. The slave acknowledges the register pointer.
6. The master sends a data byte.
7. The slave acknowledges the data byte. The next rising edge on SDA loads the data byte into its target register and the data becomes active.
8. Steps 6 to 7 are repeated as many times as the master requires. During the last acknowledge related clock pulse, the master can issue an ACKNOWLEDGE or a NOT ACKNOWLEDGE.

The master sends a STOP condition or a REPEATED START condition. Issuing a STOP ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START leaves the bus input filters in their current state.

Figure 10. Writing to a Single Register with Write Byte Protocol

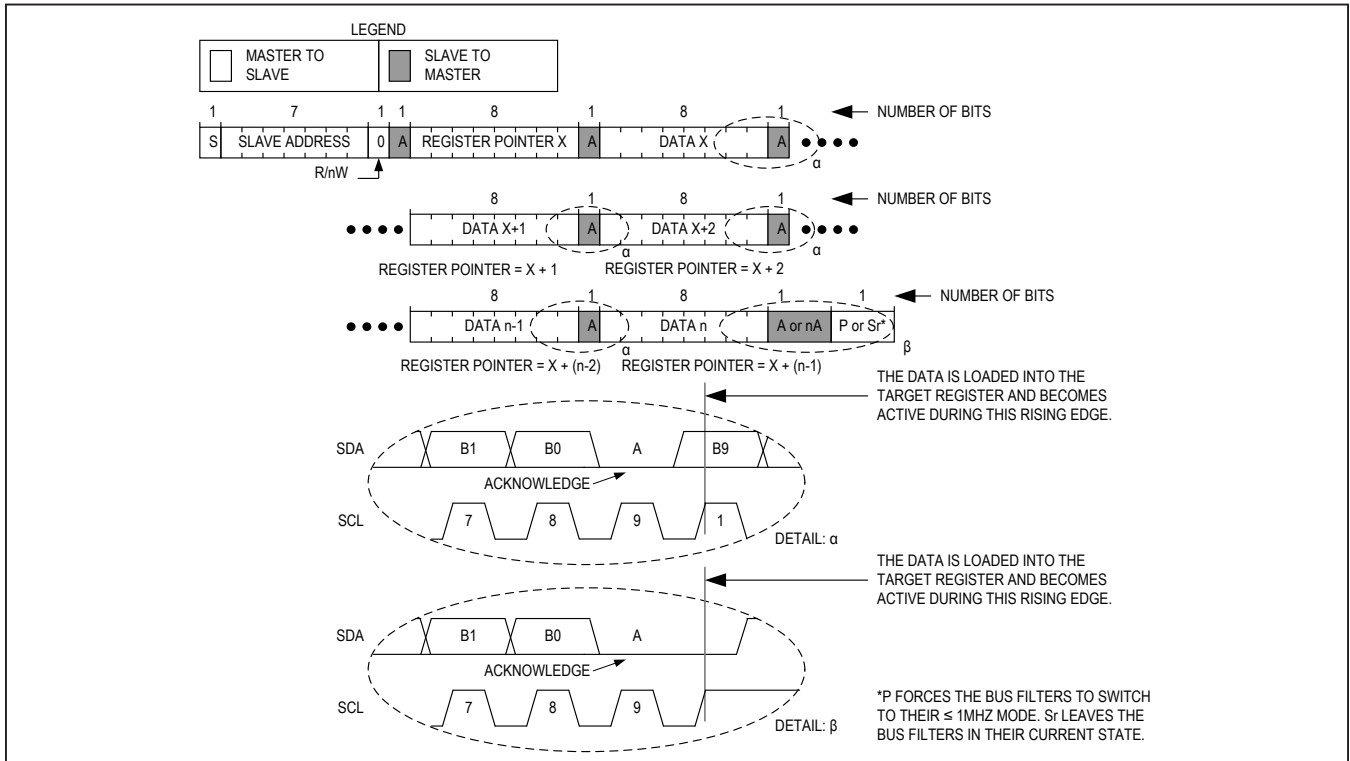

Figure 11. Writing to Sequential Registers X to N

Writing Multiple Bytes Using Register-Data Pairs

The figure below shows the protocol for I²C master device to write multiple bytes to the MAX77801 using register-data pairs. This protocol allows I²C master device to address the slave only once and then send data to multiple registers in a random order. Registers can be written continuously until the master issues a STOP condition.

The multiple byte register-data pair protocol is as follows:

1. The master sends a START command.
2. The master sends the 7-bit slave address followed by a write bit.
3. The addressed slave asserts an ACKNOWLEDGE by pulling SDA low.
4. The master sends an 8-bit register pointer.
5. The slave acknowledges the register pointer.
6. The master sends a data byte.
7. The slave acknowledges the data byte. The next rising edge on SDA loads the data byte into its target register and the data becomes active.
8. Steps 5 to 7 are repeated as many times as the master requires.

The master sends a STOP condition. During the rising edge of the stop related SDA edge, the data byte that was previously written is loaded into the target register and becomes active.

Reading from a Single Register

I²C master device reads one byte of data to the MAX77801. This protocol is the same as SMBus specification's read byte protocol.

The read byte protocol is as follows:

1. The master sends a START command.
2. The master sends the 7-bit slave address followed by a write bit ($R/\bar{W} = 0$).
3. The addressed slave asserts an ACKNOWLEDGE by pulling SDA low.
4. The master sends an 8-bit register pointer.
5. The slave acknowledges the register pointer.
6. The master sends a REPEATED START command.
7. The master sends the 7-bit slave address followed by a read bit ($R/\bar{W} = 1$).
8. The addressed slave asserts an ACKNOWLEDGE by pulling SDA low.
9. The addressed slave places 8 bits of data on the bus from the location specified by the register pointer.
10. The master issues a NOT-ACKNOWLEDGE.
11. The master sends a STOP condition or a REPEATED START condition. Issuing a STOP ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START leaves the bus input filters in their current state.

Figure 12. Writing to Multiple Registers with Multiple Byte Register-Data Pairs Protocol

Every time the MAX77801 receives a STOP, its register pointer is set to 0x00. If reading register 0x00 after a STOP has been issued, steps 1 to 6 in the above algorithm can be skipped.

Reading from a Sequential Register

Figure 13 shows the protocol for reading from sequential registers. This protocol is similar to the read byte protocol except the master issues an ACKNOWLEDGE to signal the slave that it wants more data. When the master has all the data it requires, it issues a NOT ACKNOWLEDGE and a STOP to end the transmission.

The continuous read from sequential registers protocol is as follows:

1. The master sends a START command.
2. The master sends the 7-bit slave address followed by a write bit ($R/\bar{W} = 0$).
3. The addressed slave asserts an ACKNOWLEDGE by pulling SDA low.
4. The master sends an 8-bit register pointer.
5. The slave acknowledges the register pointer.
6. The master sends a REPEATED START command.

7. The master sends the 7-bit slave address followed by a read bit ($R/\bar{W} = 1$).
8. The addressed slave asserts an ACKNOWLEDGE by pulling SDA low.
9. The addressed slave places 8-bits of data on the bus from the location specified by the register pointer.
10. The master issues an ACKNOWLEDGE signaling the slave that it wishes to receive more data.
11. Steps 9 to 10 are repeated as many times as the master requires. Following the last byte of data, the master must issue a NOT ACKNOWLEDGE to signal that it wishes to stop receiving data.
12. The master sends a STOP condition or a REPEATED START condition. Issuing a STOP ensures that the bus input filters are set for 1MHz or slower operation. Issuing a REPEATED START leaves the bus input filters in their current state.

Every time the MAX77801 receives a STOP, its register pointer is set to 0x00. If reading register 0x00 after a STOP has been issued, steps 1 to 6 in the above algorithm can be skipped.

Figure 13. Reading Continuously from Sequential Registers X to N

Engaging HS Mode for Operation Up to 3.4MHz

The figure below shows the protocol for engaging HS mode operation. HS mode operation allows for a bus operating speed up to 3.4MHz.

The engaging HS mode protocol is as follows:

1. Begin the protocol while operating at a bus speed of 1MHz or lower
2. The master sends a START command.
3. The master sends the 8-bit master code of 00001xxx where xxxb are don't care bits.
4. The addressed slave issues a NOTACKNOWLEDGE.

5. The master can now increase its bus speed up to 3.4MHz and issue any read/write operation.

The master may continue to issue high-speed read/write operations until a STOP is issued. Issuing a STOP (P) ensures that the bus input filters are set for 1MHz or slower operation. After a STOP has been issued, steps 1 to 6 in the above algorithm can be skipped.

Registers

Register Reset Conditions
